1 Quicksort

1.1 Pseudocode

Algorithm 1 Quicksort

```

procedure QUICKSORT( $A, p, r$ )
  if  $p < r$  then
     $q \leftarrow \text{PARTITION}(A, p, r)$ 
    QUICKSORT( $A, p, q - 1$ )
    QUICKSORT( $A, q + 1, r$ )
  end if
end procedure

function PARTITION( $A, p, r$ )
   $X \leftarrow A[r]$ 
   $i \leftarrow p - 1$ 
  for  $j = p$  to  $r - 1$  do
    if  $A[j] \leq X$  then
       $i \leftarrow i + 1$ 
       $A[i] \leftrightarrow A[j]$ 
    end if
  end for
   $A[i + 1] \leftrightarrow A[r]$ 
  return  $(i + 1)$ 
end function

```

1.2 Analysis

The worst case is when the pivot is either in the *first* or *last* index, best case is when the pivot is the *median* index, and the "average" case is when the pivot is between the first/last and median index (here q will represent the *true* average).

1.2.1 Worst Case:

As a recurrence,

$$\begin{aligned} T(n) &= T(n-1) + n - 1, \quad T(0) = T(1) = 0 \\ &= \sum_{i=1}^{n-1} i = \frac{(n-1)n}{2} \end{aligned}$$

1.2.2 Best Case:

As a recurrence,

$$\begin{aligned} T(n) &= 2T\left(\frac{n}{2}\right) + n - 1, \quad T(0) = T(1) = 0 \\ &= n \lg n - n + 1 \end{aligned}$$

Note: This is the same recurrence as Mergesort!

1.2.3 Average Case:

As a recurrence,

$$T(n) = T\left(\frac{n}{4}\right) + T\left(\frac{3n}{4}\right) + n - 1, \quad T(0) = T(1) = 0$$

Solve with Strong Constructive Induction.

Guess: $T(n) \leq an \lg n$ for $n \geq 1$ and some constant a .

Base case $n = 1$: $an \lg n = a \cdot 1 \cdot 0 = 0$, $T(1) = 0$ and $0 \leq 0$.

Inductive Hypothesis: Assume true for $< n$, $T(k) \leq ak \lg k$ for $1 \leq k \leq n$.

Inductive Step:

$$\begin{aligned} T(n) &= T\left(\frac{n}{4}\right) + T\left(\frac{3n}{4}\right) + n - 1 \\ &\leq a \frac{n}{4} \lg\left(\frac{n}{4}\right) + a \frac{3n}{4} \lg\left(\frac{3n}{4}\right) + n - 1 \quad \text{by IH} \\ &\leq a \frac{n}{4} (\lg n - \lg 4) + a \frac{3n}{4} (\lg 3 + \lg n - \lg 4) + n - 1 \\ &\leq \frac{an}{4} (\lg n - 2) + \frac{3an}{4} (\lg 3 + \lg n - 2) + n - 1 \\ &\leq \frac{an \lg n}{4} - \frac{2an}{4} + \frac{3an \lg 3}{4} + \frac{3an \lg n}{4} - \frac{2 \cdot 3an}{4} + n - 1 \\ &\leq an \lg n + \left(-\frac{a}{2} + \frac{3a \lg 3}{4} - \frac{3}{2}a + 1\right) n - 1 \\ &\leq an \lg n + \left(\left(\frac{3 \lg 3}{4} - 2\right)a + 1\right) n - 1 \end{aligned}$$

It follows that we need

$$\left(\frac{3 \lg 3}{4} - 2\right) a + 1 \leq 0 \implies a \geq \frac{1}{2 - \frac{3 \lg 3}{4}}$$

$$a \gtrsim 1.23$$

Thus,

$$T(n) \lesssim 1.23n \lg n$$

1.2.4 True Average Case:

As a recurrence,

$$\begin{aligned} T(n) &= \left[\sum_{q=1}^n \frac{1}{n} (T(q-1) + T(n-q)) \right] + n - 1, \quad T(0) = T(1) = 0 \\ &= \frac{1}{n} \sum_{q=1}^n (T(q-1) + T(n-q)) + n - 1 \\ &= \frac{1}{n} \sum_{q=1}^n T(q-1) + \frac{1}{n} \sum_{q=1}^n T(n-q) + n - 1 \\ &= \frac{1}{n} \sum_{q=0}^{n-1} T(q) + \frac{1}{n} \sum_{q=0}^{n-1} T(q) + n - 1^* \\ &= \frac{2}{n} \sum_{q=0}^{n-1} T(q) + n - 1 \end{aligned}$$

*Note that:

$$\begin{aligned} \sum_{q=1}^n T(q-1) &= T(0) + T(1) + T(2) + \cdots + T(n-1) \\ \sum_{q=1}^n T(n-q) &= T(n-1) + T(n-2) + T(n-3) + \cdots + T(0) \end{aligned}$$

Solve with Strong Constructive Induction.

Guess: $T(n) \leq an \lg n$ for $n \geq 1$ and some constant a .

Base case $n = 1$: $an \lg n = a1 \lg 1 = a \cdot 1 \cdot 0 = 0$, $T(1) = 0$ and $0 \leq 0$.

Inductive Hypothesis: Assume true for $< n$, $T(k) \leq ak \lg k$ for $1 \leq k \leq n$.

Inductive Step:

$$\begin{aligned}
T(n) &= n - 1 + \frac{2}{n} \sum_{q=0}^{n-1} T(q) \\
&= n - 1 + \frac{2}{n} \sum_{q=1}^{n-1} T(q) \\
&\leq n - 1 + \frac{2}{n} \sum_{q=1}^{n-1} aq \lg q \quad \text{by IH} \\
&\leq n - 1 + \frac{2a}{n} \int_1^n x \lg x dx \quad \text{by integral bound} \\
&= n - 1 + \frac{2a}{n} \left[\frac{x^2 \lg x}{2} - \frac{x^2 \lg e}{4} \right] \Big|_1^n \\
&= n - 1 + an \lg n - \frac{an \lg e}{2} + \frac{a \lg e}{2n} \\
&= an \lg n + \left[1 - \frac{a \lg e}{2} \right] n - 1 + \frac{a \lg e}{2n}
\end{aligned}$$

It follows that we need

$$1 - \frac{a \lg e}{2} \leq 0 \implies a \geq \frac{2}{\lg e}$$

So set $a = \frac{2}{\lg e} \approx 1.39$, we then need

$$\frac{a \lg e}{2n} - 1 \leq 0 \iff \frac{2 \lg e}{(\lg e)2n} - 1 \leq 0 \iff \frac{1}{n} - 1 \leq 0$$

Thus,

$$T(n) \lesssim 1.39n \lg n$$

We can realize a more natural formula,

$$T(n) \leq an \lg n = \frac{2n \lg n}{\lg e} = 2n \ln n$$

Theorem

The expected number of comparisons for Quicksort is $\approx 2n \ln n$.

1.2.5 Blum's Exact Average Case:

Let $P(i, j)$ be the probability that the i th smallest and j th smallest elements are compared.

Theorem

The average number of comparisons for quicksort is

$$\sum_{1 \leq i < j \leq n} P(i, j)$$

Only matters the first time an element from $A[i], \dots, A[j]$ is picked as pivot. The probability that the i th and j th smallest elements are compared during the execution of quicksort is:

$$\frac{2}{j - i + 1}$$

Then,

$$\begin{aligned} \sum_{1 \leq i < j \leq n} P(i, j) &= \sum_{i=1}^n \sum_{j=i+1}^n P(i, j) = \sum_{i=1}^n \sum_{j=i+1}^n \frac{2}{j - i + 1} \\ &= 2 \sum_{i=1}^n \sum_{j=i+1}^n \frac{1}{j - i + 1} \\ &= 2 \sum_{i=1}^n \left(\frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n - i + 1} \right) \\ &= 2 \sum_{i=1}^n (H_{n-i+1} - 1) = 2 \sum_{i=1}^n H_{n-i+1} - 2 \sum_{i=1}^n 1 \\ &= 2(H_n + H_{n-1} + \dots + H_1) - 2 \sum_{i=1}^n 1 \\ &= 2 \sum_{i=1}^n H_i - 2n \\ &= 2((n+1)H_n - n) - 2n \\ &= 2(n+1)H_n - 4n \approx 2n \ln n \end{aligned}$$

1.3 Comments**Quicksort Code**

Recall the Quicksort procedure,

```

procedure QUICKSORT( $A, p, r$ )
  if  $p < r$  then
     $q \leftarrow \text{PARTITION}(A, p, r)$ 
    QUICKSORT( $A, p, q - 1$ )
    QUICKSORT( $A, q + 1, r$ )
  end if
end procedure
```

When executing $\text{quicksort}(A, p, q - 1)$ we must stack up $\text{quicksort}(A, q + 1, r)$ to be executed later. We need to store the pair of index values $(q + 1, r)$.

Stack in Action

The left table represents the pivot being the largest element, and the right table represents the pivot being the smallest element.

| Pivot | Stack | Pivot | Stack |
|------------|------------------|------------|--------------|
| $A[n]$ | $(n + 1, n)$ | $A[1]$ | $(2, n)$ |
| $A[n - 1]$ | $(n, n - 1)$ | $A[2]$ | $(3, n)$ |
| $A[n - 2]$ | $(n - 1, n - 2)$ | $A[3]$ | $(4, n)$ |
| \vdots | \vdots | \vdots | \vdots |
| $A[3]$ | $(4, 3)$ | $A[n - 2]$ | $(n - 1, n)$ |
| $A[2]$ | $(3, 2)$ | $A[n - 1]$ | (n, n) |
| $A[1]$ | | $A[n]$ | |

When the pivot is the smallest element the stack remains very small but if the pivot is the largest element we stack $n - 1$ problems to do later.

In Place

On average, height of the stack for Quicksort is $\Theta(\log n)$. Height of stack for Mergesort is $\lg n + O(1)$.

Definition: An algorithm is *in place* if it uses $O(1)$ extra variables and (on average) $O(\log n)$ extra index variables.

A more technical definition is; An algorithm is *in place* if it uses at most $O(1)$ extra variables and (on average) $O((\log n)^2)$ extra bits.

Stack

We can modify the Quicksort procedure so that stack has height at most $\lg n$.

```

procedure QUICKSORT( $A, p, r$ )
  if  $p < r$  then
     $q \leftarrow \text{PARTITION}(A, p, r)$ 
    if  $q \leq (p + r)/2$  then
      QUICKSORT( $A, p, q - 1$ )
      QUICKSORT( $A, q + 1, r$ )
    else
      QUICKSORT( $A, q + 1, r$ )

```

```
        QUICKSORT( $A, p, q - 1$ )
    end if
end if
end procedure
```

Is Quicksort In Place?

Quicksort is in place, but it does not use a constant amount of extra space. Quicksort uses slightly more than a constant amount of extra space.

Choice of Pivots

It is risky to pivot on the last element because the last element could be the largest element. Some better ways could be;

- Pivot on middle element.
- Pivot on median of first, middle, and last elements.
- Pivot on random element.
- Pivot on median of three random elements.
- Pivot on median of five random elements. (Law of diminishing returns.)
- Randomly permute array before starting. (Equivalent to pivoting on random element.)

Partitioning

There are a variety of partition routines. The current edition of the textbook has a version that uses $n - 1$ comparisons, but the previous edition of the textbook has a version which uses n comparisons.
